1 Logging in Germany over the last decades

Logging is one of the most fundamental resource acquisitions in a country. Also, since transportation costs are rather high, most wood produced is logged in the same country where it is used. This makes overall logging an interesting dataset to conduct research on both the factual usage and the zeitgeist of construction in Germany. Wood is also directly coupled to the carbon footprint, whether it is the production of greenhouse gasses or CO_2 binding. In this research, I want to focus on the trends of wood production regarding its societal and climate impact using different correlation metrics as well as trend analysis.

1.1 The Data

The dataset itself contains multiple tables of wood production depicting different areas such as whole germany or its Bundesländer. Also, the data distinguishes between the different types of woods, allowing for deeper analysis on the factual usage of the resources. Since the data exclusively consists of numerical data, its main analysis will be conducted using classical numerical methods as well as statistical methods and big data analysis.

1.2 Possible Research Questions

- What is the current trend in local wood production over the last few years and over the last decade?
- Where is most wood in Germany produced and why?
- What is the carbon footprint of current wood production, and is it below reproduction levels?
